Lab report

Nuclear Magnetic Resonace

Authors:
Toni Ehmcke
Christian Siegel

Supervisor:
Samata Chaudhur

Dresden, November 29, 2015
Date of experimental procedure: November 20, 2015

Contents

1 Introduction

1.1 Motivation

Nuclear Magnetic Resonance is a physical phenomenon that can be observed while placing an ensemble of nuclei into a static magnetic field and stimulate it with a high-frequent alterning field. A necessary condition for this effect is that the atoms of the sample have a *nuclear spin* different from zero. It is the central concept that is used for *NMR-Spectroscopy*, a standard methodology for the investigation of the structure and interaction of complex molecules and solid state bodies by measuring local magnetic fields, and the *magnetic resonance tomography* which is an imaging technique used in clinical diagnistics for describing the morphilogic and physiologic build-up of tissues and organs. For all of those applications we need to find out some central parameters of particular physical compensation-processes, the so called *relaxation times* T_1 and T_2. In the following experiment exactly those material-characteristic obserables are determined for an ensemble of ^{57}Fe-nuclei. But at first some basic knowledge.

1.2 Nuclear Zeeman-Effect

2 Experimental procedure

3 Data Analysis

4 Discussion and conclusions
